

## ABSTRACT

5 A SINR measuring section 108 measures a ratio between a desired signal and an interference signal based on an output signal of an A/D converter 104 and an output signal of an interference canceller 108. An absolute electric field intensity calculator 111 calculates absolute electric field intensity of a desired signal based on said ratio between the desired signal and the interference signal and  
10 electric field intensity of said received signal. A determination section 112 determines the relationship between absolute electric field intensity of said desired signal and a preset target object in terms of the value large and small. A gain  
15 coefficient calculator 113 calculates a gain coefficient based on the determination result of the determination section 112, and controls a gain of an AGC section 103. This makes it possible to perform AGC accurately and to prevent deterioration of  
20 reception quality.
